Practical Investigation of Constraints with Graph Views

Tobias Müller

Programming Systems Lab, Universität des Saarlandes Postfach 15 11 50, D-66041 Saarbrücken, Germany Email: tmueller@ps.uni-sb.de

Abstract. Combinatorial problems can be efficiently tackled with constraint programming systems. The main tasks of the development of a constraint-based application are modeling the problem at hand and subsequently implementing that model. Typically, erroneous behavior of a constraint-based application is caused by either the model or the implementation (or both of them). Current constraint programming systems provide limited debugging support for modeling and implementing a problem.

This paper proposes the Constraint Investigator, an interactive tool for debugging the model and the implementation of a constraint-based application. In particular, the Investigator is targeted at problems like wrong, void, or partial solutions. A graph metaphor is used to reflect the constraints in the solver and to present them to the user. The paper shows that this metaphor is intuitive and proposes appraoches to deal with real-life problem sizes.

The Investigator has been implemented in Mozart Oz and complements other constraint programming tools as an interactive visual search engine, forming the base for an integrated constraint debugging environment.

1 Introduction

The state of the art of solvers based on constraint propagation has made tremendous progress [6, 17, 19, 16], to the point where large combinatorial problems can be tackled successfully. But developing such applications has only limited support by debugging tools. This deficiency has been identified and dedicated projects (as DiSCiPl [7]) have been set up.

The first step to be taken when solving a combinatorial problem is to design a constraint model of the respective problem, i.e., to find a problem formulation in terms of constraints. Next this model is implemented by some constraint solver. Testing the implementation reveals quite frequently that no solution can be found, the solution found is not correct, or the solution found still contains undetermined variables. These situations suggest that the constraint model or its implementation do not reflect the combinatorial problem to be solved. To support the development process at this stage, the programmer needs adequate interactive debugging tools which are currently not available.

Current constraint debugging tools focus on improving search behavior [18, 1, 10], i.e., on finding search heuristics¹ for exploring the search tree most efficiently. There is

In Rina Dechter, editor, *Proceedings of the Sixth International Conference on Principles and Practice of Constraint Programming – CP 2000*, volume 1984 of *Lecture Notes in Computer Science*, pages 320–336, Singapore, September 2000. Springer Verlag.

¹ A search heuristics determines the policy of traversing the search space of a problem.

a lack of intuitive interactive tools for debugging the correctness of constraint models and/or their implementations. In particular, large problems need tools with a sophisticated presentation to handle the overwhelming amount of information. Hence, providing an appropriate metaphor to present the data is crucial. The model of data presentation proposed in this paper² is derived from graph-based visualization, as proposed by Carro and Hermengildo in [2]. The graph metaphor was first formally introduced in constraint programming by Montanari and Rossi [11].

The contribution of this work is the development of different graph-based views for correctness debugging constraint programs and the proposal of debugging methodologies based on these views for frequently occurring incorrect behavior of constraint programs. Furthermore, we propose techniques for handling large problems.

To prove the viability of our approach, we have designed and implemented an interactive tool, the Constraint Investigator, that allows the user to investigate the state of constraints and variables in a constraint solver by analyzing the corresponding graph views. The Investigator is characterized by the following points:

- It is not restricted to any specific constraint system.
- It relies on a propagation-based constraint solver (see Section 3).
- It provides intuitive data presentation and interaction, while affording detailed insights about the solver.
- It is fully configurable by the user and requires no changes to the actual constraint program.
- It is suitable for users at different levels of expertise.
- It reveals operational aspects of the solver by displaying the events that trigger constraints.

The Constraint Investigator is implemented in Mozart Oz [12] and the visualization of the graph views relies on *daVinci* [4]. The Investigator complements the Oz Explorer [18], an interactive visual search engine, which does not take into account the aspect of constraint propagation. Both tools form the base of an integrated constraint debugging environment.

The Constraint Investigator can be also useful for performance debugging. For example, its graph views can be aumented with execution costs of constraints such that the program code causing these costs can be identified. Furthermore, operational aspects of constraint execution (see Section 3 about events) are revealed and can be used to improve execution performance.

Plan of the Paper Section 2 discusses issues of debugging constraint programs. Section 3 introduces notions and concepts of propagation-based constraint solving. The model of the Constraint Investigator is discussed in Section 4. The Investigator itself is explained by means of a prototypical debugging session in Section 5. Section 5 proposes also techniques for handling large problems. The paper closes with related work (Section 6) and concluding remarks (Section 7).

2 Debugging Constraints

Debugging an application focuses first on correctness and then on performance. Approaches to debugging can be identified as *experimental* and *analytic* [10]. Experimen-

² Note that [13] is a previous version of this paper.

tal debugging, i.e., modifying the program text until it seems to work, requires a large set of methods to experiment with. In contrast, analytic debugging needs to obtain a detailed description of the state of the constraint solver. Such a description has to be presented to the programmer by a debugging tool in a way that supports program analysis in the best possible fashion.

After designing and implementing the constraint model of a given problem, testing the implementation typically produces erroneous situations as:

- The solver fails immediately, i.e., the constraints are inconsistent. Either the implementation of the constraint model is incorrect or the model itself is. It is often the case that by accident the constraint model is over-constrained though the combinatorial problem is not. For example, the model states an equivalence where an implication is required. In such a case, if a solution is available (perhaps manually derived), it is a promising strategy to debug this situation by adding this solution to the constraint statements. The propagator which is observed to fail is not necessarily the culprit for the bug in the implementation but it helps to track down the problem in the constraint model.
- Propagation is incomplete in the sense that some solution variables remain undetermined. This is an indicator that the implementation or the model is incomplete.
- The solution found is wrong. Either the constraint model is incorrect or if this is not the case, the implementation of the model is incorrect.

The proposed debugging approach and the corresponding tool are aimed at analytic correctness debugging, i.e., to spot bugs in the constraint model and its implementation.

Analytic debugging requires an interactive tool that enables the programmer to analyze the actual constraints in the solver. The amount of information, i.e., typically the number of variables and constraints, is huge. The way these data are presented in analytic debugging is important since constraint programs are data-driven and an appropriate presentation helps the programmer to draw the right conclusions. Hence, data representation has to match the programmer's intuition of constraints in a constraint solver. Consequently, we choose a graph-based metaphor for representation since it makes possible to emphasize different aspects of the state of a constraint solver appropriately (see the different views presented in Section 4) and to relate the program structure to the representation (see Section 5.2).

3 A Model for Propagation-based Constraint Inference

Propagation-based constraint inference involves a *constraint store*, holding so-called *basic* and *non-basic* constraints. A basic constraint is of the form x = v (x is bound to a value v), x = y (x is equated to another variable y), or $x \in B$ (x takes its value in B).

Non-basic constraints, as for example " \neq ", are more expressive than basic constraints and hence, require more computational effort. A non-basic constraint is implemented by a *propagator* which is a concurrent computational agent observing the basic constraints of its *parameters* (which are variables in the constraint store). The purpose of a propagator is to infer new basic constraints for its parameters and add them to the store. A propagator terminates if it is inconsistent with the constraint store (failed) or if it is explicitly represented by the basic constraints in the store (entailed). A non-terminated propagator is either sleeping or running. A so-called *event* triggers the transition from sleeping to running. An event occurs when a basic constraint is added to the store. For example, a propagator might wait for a parameter to be bound to a value, while a different propagator has to be rerun as soon as an element is removed from a basic constraint connected to one of its parameters.

The constraints of a problem instance can be regarded as a network of propagators P, variables V, and events E. The variables in V are the parameters of the propagators in P. The events in E denote the changes to the basic constraints that trigger propagator transitions from sleeping to running. A propagator $p(v_1^{e_1 \in E_p}, \ldots, v_n^{e_n \in E_p})$ has a set of parameters $V_p = \{v_1, \ldots, v_n\} \subseteq V$ and is triggered by the events $E_p \subseteq E$. The notation $v_i^{e_i \in E_p}$ means that the propagator p is rerun as soon as event e_i occurs at parameter v_i . A variable $v(p_1^{e_1 \in E_v}, \ldots, p_m^{e_m \in E_v})$ is a parameter of the propagators $P_v = \{p_1, \ldots, p_m\} \subseteq P$ and changes to the basic constraint at v can cause the events $E_v \subseteq E$. The notation $p_i^{e_i \in E_v}$ means that the propagator p_i is rerun as soon as event e_i occurs at the variable v.

4 Graph-based Visualization of Constraints

In this section, we illustrate different graph views using a trivial scheduling application. The problem is to serialize two tasks, such that they do not overlap. The first (second) task starts at starting time TI (T2) and has a fixed duration of DI (D2). The corresponding constraint model is the disjunction $TI + DI \le T2 \lor T2 + D2 \le TI$. The concrete implementation uses reified constraints to implement the disjunction. A reified constraint has an extra boolean parameter that reflects the validity of the constraint, i.e., whether it is entailed or failed. For example, $BI = (TI + DI \le T2)$ is the reified version of $TI + DI \le T2$ and if this constraint is entailed (failed) BI is bound to 1 (0). Conversely, in case BI is bound to 1 (0) the constraint $TI + DI \le T2$ (TI + DI > T2) is stated. The (exclusive) disjunction of the constraints can be implemented by stating that the sum of the boolean variables associated with the reified constraints is 1. The following Oz code implements the serialization constraint for two tasks ³:

В1	=:	(T1	+	D1	=<:	Т2)	00	implemented	by	FD.reified.sumC
В2	=:	(Т2	+	D2	=<:	T1)	00	implemented	by	FD.reified.sumC
В1	+ 1	32 =	: 1				8	implemented	by	FD.sumC

We present four different views of the above constraint program. The shape of a node represents its kind: a propagator node is a rectangle, a variable node is an ellipse, and an event node is a rhombus. A propagator node is annotated with the name of the respective propagator and the location of the propagator invocation in the source program, i.e., the file name and the line number. A variable node is annotated with the name of the respective variable and if the variable is constrained, the basic constraint connected to the variable is also shown. Note that there are no variable nodes for D1 and D2 since they denote integers.

The Propagator Graph View A propagator graph is the graphical representation of a propagator net, i.e., the propagators are the nodes. Note that the edges are not di-

³ Note that D1 and D2 refer to integers and all other variables are finite domains. The =- constraint is implemented by Oz's finite domain operator =: (and \leq by =<:).

rected since data flow between propagators is bidirectional. This, for example, is dif-

ferent for a constraint solver using indexicals [3] because an indexical is a function rather than a relation. For instance,

FD.sumC opi.oz:260 FD op	D.reified.sumC pi.oz:259	D.reified.sumC pi.oz:258
--------------------------------	-----------------------------	-----------------------------

the leftmost node corresponds to the propagator FD.sumC which happens to occur at line 260 of file opi.oz (the location of FD.sumC when we did the example graph views). This annotation depends on the concrete location of a propagator in a source file. An edge between two nodes means that the propagators share at least one variable parameter.

Using the sets *P*, *V*, and *E* defined in Section 3, a propagator graph $pg(P_{pg})$ consists of nodes $N_{pg} = P_{pg}$ and edges $E_{pg} = \{(p_i, p_j) | V_i \cap V_j \neq \emptyset \land i < j\}$.

The Single Propagator Graph View A single propagator view presents a single propagator and its parameters as a tree.

The parameters are grouped by the events. Note a variable may occur several times as parameter. The single propagator graph view of FD.reified.sumC shows that the propagator waits for two events, namely the bounds-event, i.e., the bounds of the domain are narrowed, and the any-

event, i.e., an arbitrary element is removed from the domain. Furthermore, the view shows that a bounds event at the parameters T1 resp. T2 and an any event at B1 cause a rerun of the propagator. A variable node is annotated, as for example the node for T1: $T1{0\#5}$. This means that T1 takes a value from ${0,1,2,3,4,5}$. The asterisk ('*') denotes a variable passed directly by the user to the Investigator in contrast to variables collected while traversing the constraint network.

More formally, a single propagator graph spg(p) for a propagator p is a tree with a root node $R_{spg} = p$, connected to the root node are event nodes $E_{spg} = E_p$ and connected to the event nodes variable nodes $V_{spg} = V_p$. An edge between an event node and a variable node is established if the events of the event node and variable node are the same.

The Variable Graph View A variable graph view is dual to the propagator graph view. The nodes represent the variables.

An edge between two variable nodes indicates that the variables are simultaneously constrained by one or more propagators.

The information of what propagators are concerned is available by a menu associated with the edge. The variable graph view shows that in our example, all variables are connected with each other.

The formal description of a variable graph makes the duality to a propagator graph obvious: a variable graph $vg(V_{vg})$ is composed by the nodes $N_{vg} = V_{vg}$ and the edges $E_{vg} = \{(v_i, v_j) | P_i \cap P_j \neq \emptyset \land i < j\}$. An edge between two variable nodes is present if the respective variables share at least one propagator.

The Single Variable Graph View A single variable graph view represents a constrained variable, events it can cause and the propagators waiting for these events to happen. One

can see that the two reified propagators wait for the bounds event and no propagator waits either for the any event nor for the val event.

A single variable graph svg(v) of a variable v is a tree with a root node $R_{svg} = v$. Event nodes $E_{svg} = E_v$ are connected to the root node. Furthermore, each event node of an event e is connected

to the propagator nodes $P_{svg}^e = \{p^e | p^e \in P_v\}$, i.e., an edge between an event node and a propagator node is established if the propagator waits for this event to happen to this variable.

5 Correctness Debugging with the Constraint Investigator

This section introduces the *Constraint Investigator* as an interactive tool for debugging practical constraint problems. Using the Investigator does not require any changes to the constraint program. The program has to be recompiled with appropriate compiler switches.

5.1 An Example Session with the Investigator

We start off with a deliberately buggy constraint model and program and demonstrate how to track down two hidden bugs. Of course, the bugs are trivial to fix for experienced programmers but the approaches demonstrated are suitable for handling real-life situations.

The Problem Consider the following bin-packing problem: a given set of weighted items *I* has to be assigned to three bins $b_{1,2,3}$, without exceeding the maximum capacity of each bin. All bins have the same maximum capacity *c*. Furthermore, as soon as at least two items are put into a bin one extra unit of packaging material must be added as protection. Moreover, the bins must be color-coded to indicate the presence of a fragile item.

The Constraint Model The given problem is a set partitioning problem of three sets with extra constraints. Each bin b_n is modeled as set s_n and each item $i \in I$ has a weight w_i .

 $\begin{array}{ll} I = \uplus s_n & (1) & |s_n| \geq 2 \leftrightarrow \text{packaging material} \in s_n & (2) \\ \Sigma_{\forall i \in s_n} w_i \leq c & (3) & i_{fragile} \in s_n \rightarrow color(s_n) = red & (4) \\ & \text{where} & n = 1, 2, 3. \end{array}$

Constraint (1) states a set partitioning and Constraint (2) adds extra packaging if necessary. Furthermore, Constraint (3) enforces that the capacity of the bins is not exceeded and takes also into account packaging material added by Constraint (2). The coloring of the bins is modeled by Constraint (4). The model is not quite correct as we will see later on.

The Implementation of the Constraint Model The implementation of the presented model is based on finite set constraints [9, 15], i.e., a set value is approximated by a lower bound set and a upper bound set. The constraint solver has been implemented by the procedure BinPacking:

proc {BinPacking Weights Capacity Sol}

The argument Weights is a list of pairs Id#Weight. The variable Capacity determines the maximum capacity of the bins. The solution is returned in Sol and contains the colored bins with the assigned items.

The procedure starts with variable definitions: it declares the variables Red and Green for the bin-coloring constraint for the fragile item defined by Fragile. Next, it adds for the packaging material an extra item (Packaging=100) with weight 1 to the list of all weighted items AllWeights. The list of Items is extracted from the weight list (AllWeights).

```
Red = 0 Green = 1 Fragile = 1 Packaging = 100
WeightedPackaging = [Packaging#1]
AllWeights = {Append WeightedPackaging Weights}
Items = {Map AllWeights fun {$ E} E.1 end}
in
```

The body of the procedure starts by creating the solution list Sol of length 3. Each list element represents a bin as a record bin(items:S color:C) where S is the set of items and C is the color of the bin. The application of {FS.var.upperBound Items} constraints S to the set constraint $\emptyset \subseteq S \subseteq setof(Items)$.

```
Sol = {List.make 3}
{ForAll Sol
fun {$}
S = {FS.var.upperBound Items} C = {FD.int [Red Green]}
in bin(items: S color: C) end}
```

Next the partitioning constraint is stated (FS.partition). The Map function extracts the sets that form the partition from the bin records. The variable Items is converted to a set value by FS.value.make representing the set to be partitioned.

```
% constraint (1): partitioning
{FS.partition
 {Map Sol fun {$ S} S.items end} {FS.value.make Items}}
```

The weight restriction constraint maps the presence of elements to the list of boolean variables BL by FS.reified.areIn. The constraint {FD.sumC ... `=<:` ...} enforces that the scalar product of the list of boolean variables BL and the corresponding list of weights (produced by Map) does not exceed Capacity.

The constraints for adding packaging material and assigning the bin color close the procedure and use reified constraints. Reified propagators are used to conditionally state constraints according to constraint (2) in the constraint model. As soon as the cardinality of S.items is at least 2 the item Packaging is added to S.items. This is caused by the connection through the boolean variables of the reified constraints.

```
% constraint (2): add extra packaging material
{ForAll Sol proc {$ S}
```

({FS.card S.items} >=: 2) =:
{FS.reified.include Packaging S.items} end}

The constraint for coloring the bins also uses reified constraints and implements the " \rightarrow "-operator of constraint (4) by the implication constraint FD.impl⁴.

end % BinPacking

The code for controlling search is omitted since it is not of interest here and we assume an adequate search strategy. Now we submit our bin-packing solver to a search engine, like the Oz Explorer (see Figure 8 in Section 5.3):

{ExploreOne {BinPacking [1#3 2#2 3#2 4#6 5#2 6#4 7#3 8#5] 10}}

This results in an immediately failed search tree. The Investigator is now demonstrated in a prototypical debugging session.

The Implementation is not Faithful to the Constraint Model Invoking the Investigator from the failed node switches the Investigator to the single propagator graph view (see Figure 1). The node representing the failed propagator is colored red throughout the session.

Fig. 1. Single propagator view of the failed propagator FS.partition.

The single propagator graph view in Figure 1 shows the partition propagator with its parameters connected via the lowerbound event. The parameters are set constraint variables and are represented by $S\{\{100\}..\{1\#8\ 100\}\}\#\{2\#9\}^5$. This corresponds

 $^{^4}$ This is a reified constraint such that the last parameter 1 is required.

⁵ That all variables have the same name S does not mean that they are equal. The name is derived from the source code of constraint (1), cf. {FS.partition {Map Sol **fun** {\$ S} S.items **end**} ...}.

to the basic constraint $\{100\} \subseteq S \subseteq \{1, \dots, 8, 100\} \land 2 \leq |S| \leq 9$. We notice that all three parameters contain at least element 100. Hence, the partitioning propagator must fail. This reveals an incorrectness but this is not necessarily the actual bug. A single click on the propagator node highlights the line of source code where the partitioning propagator is stated (see Figure 2).

Fig. 2. Associating the failed propagator to the source program.

We see that the parameters concerned are the sets of items for each of the bins in the solution Sol. Checking the program text suggests that only the implementation of the packaging constraint (3) adds to all item fields of Sol the element Packaging (which is 100). Verifying the code for adding extra packaging material reveals the bug in the implementation: instead of using different packaging material for each bin, the same material is used for all bins. This is not the intention of the constraint model and hence an implementation bug. The bug fix simply consists of using different packaging material items for each bin and modifies the ForAll – loop to select for different bins different packaging material.

```
% packaging material for every bin
WeightedPackaging =
  [(Packaging+1)#1 (Packaging+2)#1 (Packaging+3)#1]
...
{List.forAllInd Sol
proc {$ I S} % 'I' counts from 1 to length of 'Sol'
  % select different packaging material by the index I
  ({FS.card S.items} >=: 2) =:
        {FS.reified.include 100+I S.items} end}
```

After fixing the implementation bug, we obtain as solution

and we notice that not all variables are bound to a single value (observe the color fields). The next section demonstrates how to track down the reason for this problem.

Identification of Remaining Propagators A solution with unbound variables suggests that there is a lack of propagation. The variable graph view shown in Figure 3 is produced when starting the Investigator from the solution node of the Explorer.

The variable Sol is not displayed because it is bound to the solution list and hence no variable anymore. We try to find remaining propagators starting from one of the variable nodes. We decide to switch to the variable graph view of all reachable variables

Fig. 3. Initial view.

(Figure 4(a)), to get an overview over all variables left unbound. The menu associated with an edge between two variable nodes (Figure 4(b)) offers to switch to a single propagator graph view of a propagator being imposed upon two variables.

(a) Variable graph view of all reachable variables.

(b) Edge menu of the variable graph view.

Fig. 4. Variable graph view.

Since we try to find remaining propagators, we switch to the offered single variable graph view of a reified sum propagator (Figure 5).

A click on the propagator node immediately reveals the suspicious program text: the assignment of the bin colors seems to be too weak whenever a fragile item is not contained in a bin (implementation of constraint (4)). The problem can be fixed by replacing the implication by an equivalence (FD.equi). The correct constraint (4) in the constraint model is $\forall n : i_{fragile} \in s_n \leftrightarrow color(s_n) = red$. That means that the implementation was correct but the constraint model had a flaw. After applying the fix the solver produces a proper solution.

5.2 Approaches for Dealing with Realistic Applications

Realistic problems may have thousands of propagators and variables. It is impossible and without any practical use to represent all at once. This section proposes techniques

Fig. 5. Single propagator graph view.

for selecting problem-relevant fractions of propagators or variables. This scheme allows for a user-controlled incremental exploration of the graphs which is essential for the investigation of large problems.

A common approach of designing a constraint model is to decompose the problem into subproblems and to decompose these subproblems until predefined propagators can be used. Since procedures implement subproblems, it seems reasonable to structure propagators, sub-procedures, and variables according to the procedures which stated them. This requires the introduction of procedure nodes to the graph views. A procedure node is depicted as circle.

Selection via the Tree of Execution Traces The tree representation of a constraint program's execution trace (see Figure) is used to select propagators and \bigcirc

variables. By clicking on a node, a possible action is to select the propagators under agators created by the corresponding procedure invocation. Incremental expansion of the tree makes possible to handle large collections of propagators and variables. Different selection schemes, e.g., all propagators stated by a procedure with respectively without their sub-procedures, extend the functionality.

Collapsing and Expanding Propagator and Procedure Nodes A common technique for handling large collections of data represented by graphs is to collapse and expand appropriate subsets of nodes to single nodes. We propose for the propagator graph view to determine subsets of nodes according to the procedures which created them. That means a collapsed node represents a collection of propagators and sub-procedures. This is very close to the model the programmer has in mind when structuring the problem and hence, is very intuitive.

A procedure node represents a collection of propagator nodes and sub-procedure nodes. It takes as its parameters the union of the parameters of all represented propagators and sub-procedures.

(a) Fully collapsed procedure graph, i.e., all propagator nodes are collapsed.

(b) Partially collapsed propagator graph, i.e., a procedure's node is expanded to its propagator nodes.

Fig. 6. Transition of a graph view by expanding a procedure node.

Figure 6 shows the expansion of the marked procedure node to a collection of propagator nodes. Expansion can be undone by collapsing propagator and procedure nodes to a single procedure node.

Filtering Propagators and Variables Another interesting feature is the option of displaying only those propagators resp. variables which meet a criterion specified by the user. For example, it might be interesting to limit the investigation to those propagators that are connected to boolean variables when symptoms of a bug suggest that.

5.3 Additional Features

This section discusses features of the Investigator not covered before but important for effective use of the tool.

Navigating Through Graphs Navigation through the different graph views is done by menus associated with nodes and edges of the respective views. Figure 7 shows possible transitions from one view to another one. A history mechanism is also available, allowing to recall previous views by moving in the chain of views produced so far.

Fig. 7. Navigation overview.

To further improve navigation and to keep track of a certain node in different views, the Investigator is able to mark nodes in graph views which then remain marked throughout all views.⁶ Additionally, the Investigator automatically marks nodes of variables with which the session was initiated (Figure 3) and in case there is a failed propagator, the node of this propagator (Figure 1).

Changing the Representation of Nodes The Investigator provides a plug-in mechanism for changing the representation of variables and propagators. This enables the user to produce a more obvious and intuitive representation. For example, a propagator for a constraint in a scheduling application might be represented as Gantt-chart, reflecting its role in the concrete application.

Interaction with the Oz Explorer The gine where the user can control search. It visualizes the search tree as search proceeds. The shape of a node tells the user whether a node denotes either a failure (square resp. a triangle for a failed subtree), a solution (rhombus), or a choice (circle). By default, clicking an Explorer node displays the basic constraints of the corresponding constraint store. This action can be modified by plugs-ins as the Investigator is one (as demonstrated in Section 5.1).

Fig. 8: The Oz Explorer

⁶ For the purpose of this paper, a marked node is drawn with double lines. Other schemes, for example using colors, might be more suitable in connection with color displays.

6 Related Work

The tools discussed in this section focus on improving performance. Since our approach is orthogonal, it can be used to supplement existing tools.

The Grace constraint debugger by Meier [10] supplements the Prolog-based constraint programming system $ECL^{i}PS^{e}$ [8] and is intended to support performance debugging of finite domain constraint programming. The constraint program has to be appropriately instrumented to be run under Grace. The debugging model of Grace is based upon the Prolog-box-model. It is able to follow individual propagation steps in the trace and to inspect the backtrack stack of finite domain variables. Furthermore, Grace is highly configurable by assigning user-written code to each propagation step.

The search tree debugger of Chip [1,5] is largely influenced by the Oz Explorer⁷. Its focus is performance debugging. It provides different types of views, mostly in a compact matrix-like fashion, to provide the user with more detailed information about search and constraint propagation. A nice feature is to analyze the evolution of constraints and variables along a search path. This is certainly most valuable for optimizing search heuristics.

7 Conclusion

We have presented a novel approach for correctness debugging constraint programs based on graph views. Based on this approach, we have implemented an interactive tool, the Constraint Investigator. The use of the Investigator has been demonstrated with an example derived from a realistic constraint programming application. The Investigator has been tested with problems of medium size (500 propagators and 600 variables) and has helped to understand and to debug the constraint-based implementation of a natural language parser. To our knowledge, no other interactive constraint debugging tool uses a graph metaphor in the way presented in this paper and that makes the Constraint Investigator unique.

Implementation The implementation of the Investigator is straightforward. It traverses the network of constraints in the solver starting from the solution variables to collect all propagators and variables. Thereby the implementation takes advantage of propagators being first-class values [14]. Every variable and propagator is assigned a unique integer. That makes it possible to store relations between variables and propagators in sets of integers. The computation of the different graph views follows closely the definitions of the graph views in Section 4. The complexity of the graph-generation algorithm is worst-case quadratic and depends in practice on the degree of connectivity of the constraint network, i.e., if the propagators can be stated in reasonable time then the corresponding graph can be computed in reasonable time too.

Acknowledgements I would like to thank the *daVinci* team for making this brilliant tool available. I am grateful to Leif Kornstaedt for helping me with the implementation. I am also grateful to Christian Schulte for many fruitful discussions. Denys Duchier exercised the Investigator in the development of linguistic applications and helped with invaluable comments and suggestions. The aforementioned, Katrin Erk and the anonymous referees gave invaluable comments on earlier versions of this paper.
